

METEOROLOGICAL OFFICE.

BRITISH METEOROLOGICAL AND MAGNETIC YEAR BOOK, 1917.
PART IV.

HOURLY VALUES FROM AUTOGRAPHIC RECORDS:
1917.

COMPRISING
HOURLY READINGS OF TERRESTRIAL MAGNETISM AT ESKDALEMUIR OBSERVATORY
AND
SUMMARIES OF THE RESULTS OBTAINED
IN
TERRESTRIAL MAGNETISM, METEOROLOGY, AND ATMOSPHERIC ELECTRICITY,
CHIEFLY BY MEANS OF SELF-RECORDING INSTRUMENTS, AT THE OBSERVATORIES
OF THE METEOROLOGICAL OFFICE.

IN CONTINUATION OF

The Reports of the National Physical Laboratory, 1900–1909, and (in similar form) Summaries of Results of Geophysical and Meteorological Observations, 1910, the Reports of the Kew Committee of the Royal Society, 1872–1899, and of the Kew Observatory Committee of the British Association, 1842–1871.

Published by Authority of the Meteorological Committee.

LONDON:

To be purchased from

THE METEOROLOGICAL OFFICE, AIR MINISTRY, KINGSWAY, LONDON, W.C. 2, AND EXHIBITION ROAD, LONDON, S.W. 7.
Price Twelve Shillings and Sixpence Net.

P R E F A C E.

FOR the years 1911 to 1913, "Hourly Values from Autographic Records" was published in two sections. The issue of the first section, which contained hourly values of pressure, temperature, humidity, wind, rainfall, and sunshine, is now discontinued. The present volume represents the Section 2 of those three years, and is the seventh of the series. It may be regarded as a continuation in extended form of the tables and summaries giving the results of observations in terrestrial magnetism and atmospheric electricity which were included in the reports of the committee of management of the Kew Observatory from 1842 to 1910, and of tables published by the Meteorological Office in the *Quarterly Weather Report* from 1869 to 1880, and thereafter in *Hourly Readings*.

The tables of the present volume fall into three groups. In the first group the mean daily variation of the various meteorological elements is given for each month. The figures refer to the five observatories, Aberdeen, Eskdalemuir, Cahirciveen (Valencia Observatory), Richmond (Kew Observatory), and Falmouth.

In the second group fall Tables I. to XLVIII., in which the readings of the magnetographs at Eskdalemuir Observatory for each hour throughout the year are set out, together with appropriate notes; Tables XLIX. to LXIV., giving results deduced from these readings and corresponding figures for Kew Observatory; and Tables LXVII. and LXVIII., in which magnetic data for various stations are set out.

In the third group are the three tables on page 64. These tables show the mean daily variation of potential gradient at Richmond and Eskdalemuir. The values from which the means have been computed are not published.

The tables are followed by notes on the management of the magnetic and electrical instruments and on results of interest. For notes on the meteorological instruments reference may be made to the Year Book, Part IV., Section 1, 1913, but notes on the Meteorological Summaries are included in this volume.

It is proper to add that in all matters concerning the scientific work of the observatories full advantage is taken of the advice of the Gassiot Committee, which was appointed for that purpose by the President and Council of the Royal Society in 1910, in accordance with the scheme approved by the Lords Commissioners of H. M. Treasury when the transfer of the administration of the observatories at Kew and Eskdalemuir was effected.

In particular, reference may be made to one point of great importance, namely, the units employed for the representation of the various quantities.

The letter of the Royal Society, dated 14th April 1910, which conveyed to the Meteorological Committee the information of the appointment of the Gassiot Committee, communicated also the following information as to the proceedings at the first meeting held on 13th April 1910:—

“ The question of the units employed in the international publication of meteorological observations was discussed, and it was unanimously resolved—

“(1) That in the opinion of the Gassiot Committee of the Royal Society it is essential that all meteorological returns compiled for international use should be expressed in terms of an international system of units founded on the metric system.

“(2) That a system in which the measure of barometric pressure is expressed in megadynes per square centimetre, and of temperature in absolute degrees Centigrade, would be a satisfactory one.”

In furtherance of the views expressed in these resolutions, and therefore departing from the traditional practice of printing meteorological results in Inch-Fahrenheit units in the same volume which gave electrical and magnetic results in C.G.S. units, the meteorological data have been given in C.G.S. units with temperature in absolute degrees.

In 1911, the first year of the British Meteorological and Magnetic Year Book, this principle was carried out in Part III., Section 1 (*the Geophysical Journal*), and in the two sections of Part IV. In 1912 it was adopted for Part III., Section 1 (*Daily Readings*). The expression of pressure in millibars in the *Monthly Weather Report* and in the maps of the *Weekly Weather Report*, Section 2, dates from 1914. Rainfall has been given in millimetres in the Monthly and Weekly Reports since the beginning of 1915; the use of Absolute Temperatures in the descriptive summaries and in the Tables of District-Values in those publications commenced in 1916.

Tables for conversion of meteorological data between Inch-Fahrenheit units and the units used in this publication are given in the 1913 volume and in the *Computer's Handbook*.

In carrying out the arrangement of the tables endeavour has been made to provide (1) that at the head of each column there shall be found an indication of the denomination of the units employed, and (2) that wherever the same quantity is represented the same unit shall be employed, so that the decimal point as regards a particular quantity always has the same meaning.

The exigencies of printing have made it necessary in the tables of diurnal inequalities to reduce the width of the column used to indicate the months and seasons to the space necessary for two letters at most. No difficulty can be experienced by the reduction of the names of the months to their initial letters, J., F., etc., standing for *January*, *February*, and so on, and in the same way Y. will easily be appreciated as representing *Year*. But “W.” “Eq.” and “S.” standing for *Winter*, *Equinox*, and *Summer*, require some explanation. The Winter, which “W” represents in these tables, includes the months of *November*, *December*, *January*, *February*; the Summer, *May*, *June*, *July*, *August*; and the Equinox, the remaining four months of the year, viz., *September*, *October*, *March*, and *April*.

In the magnetic tables X has been used to denote the North Component and $-Y$ the West Component, in accordance with the International practice of employing X and Y to denote the North and East Components. In the notes, however, the letters N and W have been generally employed, so as to avoid any confusion between numerical and algebraic increases in the South-North and East-West Components.

The year 1917 was the second in which "Summer Time" was introduced. The reader need not take this into consideration, however, as all the observations at the observatories are referred to Greenwich Mean Time.

Some explanation of the insistence in this volume on the references to Richmond and Cahirciveen in connection with Kew Observatory and Valencia Observatory may be desirable.

Kew Observatory is in the Old Deer Park. This Park adjoins the Royal Gardens, Kew, but access to it is by Richmond, not by Kew, so that visitors coming by railway have to be warned not to book to either of the Kew stations. It is of interest to recall that there was once an observatory at Kew, and that some of Bradley's observations which led to the discovery of aberration were made there; the site, in front of Kew Palace, is marked by a sundial.* In the instructions prepared by the King's Observer, Dr. S. C. Demailbray, for the observation of the transit of Venus in 1769, the present observatory is referred to as Richmond Observatory.

The name of Valencia Observatory can be justified on historical grounds, though not geographically. The observatory was established on Valencia Island in 1867, and the instruments were transferred to Westwood House, Cahirciveen, in 1892. The distance between the two sites is about three miles.

The publication of meteorological and geophysical data for the year 1917 is arranged in accordance with the following scheme :—

(a) DAILY WEATHER REPORT.—

The *Daily Weather Report* for 1917 contains meteorological information from nearly 130 stations in or near Europe, of which about 75 are situated in the British Isles. The data for most of the foreign stations, and nearly half the British, include morning and evening observations upon which the weather charts of North-Western Europe and the Eastern Atlantic are based. Some general information for the 24-hour period is given for all British and most foreign stations.

In accordance with regulations for the Defence of the Realm, the *Daily Weather Report* could not be supplied to the public until fourteen days after the date of issue.

(b) BRITISH METEOROLOGICAL AND MAGNETIC YEAR BOOK.—

The serial statistical publications of the Meteorological Office which have been grouped together under this title are as follows :—

* "The History of the Kew Observatory," R. H. Scott, London, *Royal Soc. Proc.*, vol. xxxix., p. 1, 1885.

Part I.—*Weekly Weather Report*, comprising Section I., Weekly results of observations of the meteorological elements for stations and districts in the British Isles; Section II., Daily Synoptic Charts of the North Atlantic Ocean and adjoining continents; Annual and Quarterly Appendices. Issued on Friday of each week. Price 6d. per number. Annual subscription (which includes the Monthly Weather Report) 30s., postage paid. The issue of Section II. has been suspended since August 1914.

Part II.—*Monthly Weather Report*, prepared for issue at the end of the month to which it refers, and uniform with a summary issued annually. Price 6d. per number.

Part III.—(1) *Daily Readings* at Stations of the First and Second Orders. Issued in monthly parts within about five weeks of the close of each month. Price 6d. each part. Annual Volume 5s.

(2) *Geophysical Journal* of the Observatories of the Meteorological Office. Issued in monthly parts. Price 1s. each part.

Part IV.—*Hourly Values* from Autographic Records. Meteorology, Terrestrial Magnetism, and Atmospheric Electricity. Issued at the end of each year. Price 7s. 6d.

Part V.—*Réseau Mondial* (Monthly and Annual Summaries of Pressure, Temperature, and Precipitation at Land Stations, generally two for each Ten-degree Square of Latitude and Longitude) has been issued for 1910, 1911, 1912, and 1913. The 1914 volume is now in the printer's hands.

The publications include the results of the work of the observatories in the departments of Meteorology, Terrestrial Magnetism, Atmospheric Electricity, and Seismology.

It can scarcely be hoped that all the difficulties in the way of adequate presentation and co-ordination of data for different branches of geophysics have been overcome, but, so far as possible, precautions have been taken to enable the reader to know exactly where he stands when he takes up any question which depends upon a comparison of the results of the observatories of the Meteorological Office *inter se*, or with those of other institutions or other countries.

NAPIER SHAW,
Director.

METEOROLOGICAL OFFICE,
SOUTH KENSINGTON, S.W. 7, *August 2nd, 1920.*

TABLE OF CONTENTS.

	PAGE
Preface	2
Table of Content	6
Geographical Position of the Observatories	7
Summary of Results in Meteorology :	
Monthly Means for each Hour for Five Observatories	8
Table of Results of Observations of Terrestrial Magnetism :	
Hourly Readings, Eskdalemuir, with absolute observations, base line values, etc.	30
Diurnal Inequalities, Eskdalemuir	54
International Quiet Days : Diurnal Inequalities, Eskdalemuir	56
Selected Disturbed Days: ,, ,, ,,	58
International Quiet Days: ,, ,, Kew Observatory	60
Range of Diurnal Inequalities	60
Harmonic Components of the Diurnal Inequality, Eskdalemuir	61
Mean Monthly and Annual Values for Meteorological Office Observatories	62
Mean Annual Values for Magnetic Observatories of the Globe	63
Summary of Results of Observations of Atmospheric Electricity :	
Diurnal Inequality of Potential Gradient at Kew Observatory	64
" " " " " Eskdalemuir, (0, α days only)	64
" " " " " (1, α and 2, α days only)	64
Notes on the Meteorological Summaries	65
Terrestrial Magnetism :	
I. Notes on the Management of the Instruments at Kew Observatory, Richmond, and on the corresponding Tables	72
II. Notes on the Magnetic Observations made at the Valencia Observatory, Cahirciveen	76
III. Notes on the Management and Manipulation of the Instruments at Eskdalemuir Observatory	77
IV. Review of Results of Magnetic Observations made at Eskdalemuir during 1917 .	80
Atmospheric Electricity :	
Potential Gradient at Kew Observatory and at Eskdalemuir in 1917	87

HOURLY VALUES FROM AUTOGRAPHIC RECORDS. 1917.

LIST OF OBSERVATORIES.

	Latitude.	Longitude.	G.M.T. of Local Mean Noon.	Height above M.S.L. in metres.
Central Observatory: Kew Observatory, RICHMOND, Surrey	51° 28' N.	0° 19' W.	12 ^h 1 ^m	5·5
Magnetic Observatory: ESKDALEMUIR, Dumfriesshire . . .	55 19 N.	3 12 W.	12 13	242·0
Western Observatory: Valencia Observatory, CAHIRCIVEEN, Co. Kerry	51 56 N.	10 15 W.	12 41	9·1
Auxiliary Observatories: ABERDEEN (Meteorology) . . .	57 10 N.	2 6 W.	12 8	14·0
FALMOUTH (Meteorology) . . .	50 9 N.	5 4 W.	12 20	50·8

Notes.—(1) The height given is that of the site of the rain-gauge. The heights of other meteorological instruments are shown under the appropriate Tables.

(2) Values printed in *italic* type in the following Tables are obtained by interpolation.

ABERDEEN.
The values for 1917 are given by the departure from the normal; + indicates excess, - defect. The pressures are for station level, corrected for temperature and gravity, measured at each exact hour, G.M.T. The normals are for the period 1871-1915. (Eskdalemuir 1911-15 only).	Mean values are calculated by the formula, mean = $\frac{1}{24} \{ (1 + \dots + 23) + \frac{1}{2}(0 + 24) \}$

The Temperature is obtained photographically from a mercurial thermometer with a large cylindrical bulb, 10 cm. long, and a long stem. The column of mercury in the stem is broken at a convenient point by a small air space, which moves up or down with the rise or fall of temperature. The bulb is exposed in a louvred screen attached to the North wall of the Observatory, except at Eskdalemuir, where the screen stands in the open, and the stem is bent twice at right angles, so that whilst one vertical portion containing the air speck is within the room where the photographic record is obtained, the other with the bulb itself is in the open air and at least 60 cm. from the wall. Two such thermometers are in the screen, one being used as a dry bulb and the other as a wet bulb; the screen also contains two control thermometers with bulbs of the same size.

NORMALS AND DEPARTURES THEREFROM IN 1917.

The heights of the thermometer bulbs above the ground are :—

At Aberdeen 12·5 metres

At Aberdeen 12.5 metre
" Eskdalemuir 0.9 "

„ Cahirciveen (Valencia Observatory) 1.3 „

,, Meckmmond (Kew Observatory) : 39

The normals for temperature are for the 45 years, 1871-1915 (Eskdalemuir, 1911-1915 only).

The values for 1917 are given by the departure from the no.

Temperature values are measured at each exact hour G.M.T.
Mean values are calculated by the formula $\frac{1}{24} \left\{ (1 + \dots + 23) + \frac{1}{2}(0 + 24) \right\}$

HOURLY VALUES OF THE METEOROLOGICAL ELEMENTS:

The Relative Humidity of the air for each hour is deduced from the readings of the dry and wet bulb thermometers (see note on p. 12) by means of Glaisher's factors, complete saturation being taken as 100.

The normals for humidity are obtained from the observations for 30 years, 1886-1915 (Eskdalemuir 1911-1915 only).

* Cahirciveen Normals for March are for 29 years only, 1892 being omitted. † The Richmond Normals for May and June are for 29 years only, 1891 being omitted.

NORMALS AND DEPARTURES THEREFROM IN 1917.

JANUARY TO JUNE.

The values for 1917 are given by the departure from the normal; + indicates excess, - defect.

The mean values are calculated by the formula, mean = $\frac{1}{24} \left\{ (1 + \dots + 23) + \frac{1}{2}(0 + 24) \right\}$

* Cahirciveen Normals for March are for 29 years only, 1892 being omitted. † The Richmond Normals for May and June are for 29 years only, 1891 being omitted.

At Aberdeen, Cahirciveen, and Richmond, the speed of the wind is obtained from the records of a Robinson cup-anemometer having cups 9 inches (0·23 metre) in diameter carried on arms measuring 2 feet (0·61 metre) from the centre of the cup to the spindle. The mean speed is found from the travel of the cups in the sixty minutes centering at the hour G.M.T., by multiplying by the factor 2·2, and is converted to metres per second.

At Eskdalemuir the speeds are obtained from the records of a Dines' pressure-tube anemometer. They represent mean values for sixty minutes centering at the hour G.M.T.

NORMALS AND DEPARTURES THEREFROM IN 1917.

The heights of the anemometers (centres of cups of Robinson anemometers) above the general surface of the ground are:—Aberdeen, 22.9 metres; Eskdalemuir, 15.0 metres; Cahirciveen, 13.9 metres; Richmond, 19.8 metres. The heights above the roofs of the buildings on which the instruments are erected are:—Aberdeen, 3.7 metres; Eskdalemuir, 6.7 metres; Cahirciveen, 2.1 metres; Richmond, 2.1 metres.

The normals for wind speed are for the 35 years, 1881-1915 (Eskdalemuir, 1911-15 only).

The values for 1917 are given by the departure from the normal; + indicates excess, - defect.

The mean values are calculated by the formula, mean = $\frac{I}{24} \left\{ (1 + \dots + 23) + \frac{1}{2}(0+24) \right\}$

HOURLY VALUES OF THE METEOROLOGICAL ELEMENTS:

WIND SPEED (in Metres per Second).

The amounts of rainfall are obtained at each observatory from the autographic records of a Beckley rain-gauge for each sixty minutes centering at the hour G.M.T.

The heights of the receiving surfaces of the gauges above the ground, and also above M.S.L., are as follows:-

Height above Ground.	Height above M.S.L.
0.6 metre	14.6 metres
0.4 "	242.3 "
0.6 "	9.7 "
0.5 "	6.0 "
0.6 "	51.4 "

Aberdeen

The values for 1917 are given by the departure from the normal; + indicates excess, - defect. Amounts of snow or rain which cannot be distributed among the actual hours of fall are omitted from the hourly means. In preparing the normals, however, an approximate allocation of such falls to their proper hours has been made.

* International quiet day.

* Note that in the previous years this value was 45,000 γ .

† Mean of 30 days; 4th omitted.

‡ Approximate value.

** Day "proposed for reproduction" by the International Magnetic Commission (double star).

* Mean of the Corrected Readings of the Thermometers in the N, W, and V Magnetograph Boxes.
 † The times are those of the Declination and Dip observations only. The Horizontal Force values given refer to the mean time of the Declination observations, being derived by a combined use of the actual observations and curve measurements.

27	11 34	12 18	16690	17 22 34	69 40.8		

MARCH, 1917.

This was one of the two quietest months of the year, the mean magnetic character figure being 0.5, while that for the year was 0.7. No large disturbances were recorded, but considerable "internal" activity was displayed on the 5th, 6th, 8th, and 25th. Bays are shown centering on the N trace at 19^h 50^m on 1st; at 10^h 35^m on 4th, accompanied by pulsations of 2^{min}. period; at 6^h 50^m on the 5th (inverted bay); at 17^h 39^m on 8th (double oscillation of range 145 γ); at 2^h 10^m on 21st (inverted bay); and at 22^h 24^m on the 25th. The W traces were unusually free from large or even moderate disturbance, the only noticeable feature being pulsatory movements during daylight hours on 1st, 4th, 5th, 6th, 13th, and 25th.

* Mean of the Corrected Readings of the Thermometers in the N, W, and V Magnetograph Boxes.
† The times are those of the Declination and Dip observations only. The Horizontal Force values given refer to the mean time of the Declination observations, being derived by a combined use of the actual observations and curve measurements.

XIII.—READINGS OF THE NORTH COMPONENT OF TERRESTRIAL MAGNETIC FORCE

24	10 17	10 46	16704	17 19 6	69 39.2		

* Mean of the Corrected Readings of the Thermometers in the N, W, and V Magnetograph Boxes.
† The times are those of the Declination and Dip observations only. The Horizontal Force values given refer to the mean time of the Declination observations, being derived by a combined use of the actual observations and curve measurements.

The month was characterised by the absence of any large disturbance and by the frequent occurrence of disturbances of low range, the only really quiet days being 10th, 11th, 14th, 20th, and 27th. Prominent bays on the N trace are shown at 19^h 56^m on the 2nd and at 0^h 51^m on the 13th; and on the W at 21^h 10^m on the 12th (inverted bay accompanied by clearly marked pulsations of 2^{min.} period). It is noticeable that the mean absolute daily range (R_n) on the N component during the month was 19 per cent. greater than that on the W component. Usually the excess of R_n over R_w is much less than this in equinoctial months.

MAY, 1917.

The principal disturbance of the month began on 30th April at 22^h 36^m, and was marked, at that time, by a sudden commencement which produced a change, in 3 minutes, of +61 γ N, +23 γ W, and -11 γ V. In the subsequent course of the disturbance, large movements took place at 22^h on the 1st and about 1^h 30^m on the 2nd, and these were most prominent on the N and W traces. The first consisted of a double oscillation whose range was 114 γ on N, and was accompanied by a sharp drop of 95 γ in V. The V trace showed no well-marked maximum during the *post-meridiem* hours of the 1st, but showed two marked minima at 22^h 28^m on 1st and 2^h 41^m on 2nd. The V traces for 2nd, 3rd, 4th, and early hours of 5th show certain similarities involving "repetitions" of a fairly easily recognisable kind. A slight disturbance, involving no movements of large range, but accompanied by numerous rapid pulsations, began with a sudden commencement at 5^h 45^m on 16th. Another sudden commencement, followed by no considerable disturbance, was recorded on 21st at 15^h 39^m. A prominent bay on the W trace, centering at 23^h 44^m on 9th, accompanied by a slow fall in V, is worth notice.

* Mean of the Corrected Readings of the Thermometers in the N, W, and V Magnetograph Boxes.
 † The times are those of the Declination and Dip observations only. The Horizontal Force values given refer to the mean time of the Declination observations, being derived by a combined use of the actual observations and curve measurements.

* Mean of the Corrected Readings of the Thermometers in the N, W, and V Magnetograph Boxes.

† The times are those of the Declination and Dip observations only. The Horizontal Force values given refer to the mean time of the Declination observations, being derived by a combined use of the actual observations and curve measurements.

JUNE, 1917.

The first of the three principal disturbances of the month began on the 6th with a sudden commencement at 17^h 10^m. The larger movements did not develop until the evening hours of the 7th. Quiet conditions were resumed by noon on the 8th, but at 0^h 6^m on the 9th another sudden commencement was recorded. The subsequent changes were of very moderate range. The 13th was a day of considerable disturbance, especially between 14^h and 18^h, in which interval six complete oscillations with an average range of 50 γ were recorded on N. The most disturbed portion

HOURLY VALUES FROM AUTOGRAPHIC RECORDS.

* Mean of the Corrected Readings of the Thermometers in the N, W, and V Magnetograph Boxes.

† The times are those of the Declination and Dip observations only. The Horizontal Force Values given refer to the mean time of the Declination Observations, being derived by a combined use of the actual observations and curve measurements.

‡ Doors of East Room of Magnet House left open.

JULY, 1917.

The month was one of an average value as regards character figure. The disturbed portions of the month fell during the days 2nd–5th, 8th, 16th–20th, 25th–26th. Sudden commencements were recorded at the following times:—2d 3h 42m, 13d 0h 25m, 27d 13h 56m, 31d 4h 40m. Following on the first of these, a disturbance of moderate

* Mean of Corrected Readings of the Thermometers in the N.W. and V Magnetograph Boxes.

[†] The times are those of the Declination and Dip observations only. The Horizontal Force values given refer to the mean time of the Declination observations, being derived by a combined use of the actual observations and curve measurements.

This month was one of large and frequent disturbance, as is shewn by the mean character figure, 1·0, and by the mean daily absolute ranges for the month, which were 172γ N; 146γ W; 124γ V. These are the largest values obtained since the beginning of the present system of observations at Eskdalemuir on 1st January 1911.

The first disturbance of the month began with a sudden commencement at $9^{\text{d}}\ 4^{\text{h}}\ 16^{\text{m}}$, and it is of some significance that the main and largest part of the disturbance followed immediately afterwards. This part consisted of a large oscillation represented (as far as departure from the undisturbed state is concerned) by clockwise described loops on the meridian and horizontal planes, and occupied $1\frac{1}{2}$ hours. Its range was $278\ \gamma$ N; $277\ \gamma$ W; $311\ \gamma$ V. This, as well as later portions of the disturbance, showed many pulsations of short period, these being shown even on the V trace. A later phase of the storm began soon after 23^{h} , and exhibited changes of unusual amount, the N trace being off the sheet for $1\frac{1}{2}$ hours about midnight. A prominent feature was the absence of any rise in V; all the changes being on the negative side of the normal value.

The storm which began soon after noon on 13th, and lasted until the evening of 15th, was one of exceptional range, especially on the N and W components. The traces for these components were off the sheet on both of the first two days of the disturbance. On both these days the V trace showed a rapid rise above the undisturbed line, but whereas during the first 24 hours there was no fall below that value—a somewhat exceptional case—in the second there was a rise to $> 138 \gamma$ above it, and a fall to 223γ below it.

The third leading disturbance began with a sudden commencement at 8^h 24^m on the 20th, but the chief movement was not developed until noon on the 21st. The rise in V was earlier than usual, and the characteristic drop in value about midnight was also earlier.

The last disturbance of the month began shortly before 20^h on 25th. The rise in V in the afternoon hours of that day had been but slight, but there was an extremely rapid fall in that element (276 γ in 35^m) about 2^h on 26th.

SEPTEMBER, 1917.

The month was of average character as regards disturbance, there being only one day (5th) on which the absolute daily range was well above normal. The disturbance of that day began suddenly at 6h 10m after a tolerably quiet interval of 12 hours, but the phenomena were unlike those of the typical sudden commencement. In N there was only a sharp drop, in W a slight rise followed by a fall and then a rise, in V a sharp rise followed by a fall. The immediately following movements were of a highly pulsatory character. The principal movement associated with this disturbance took place between 20h 16m and 21h 40m, and included two complete oscillations on N and W, the extreme ranges being 209 γ N; 146 γ W.

Numerous cases of pulsations of short period occurred during the month, one notable case being between 20h 20m and 20h 42m on 20th, in which interval 25 pulsations were counted on the W trace.

A doubtful sudden commencement, not followed by any disturbance, is noted at 13h 48m on 28th.

* Mean of the Corrected Readings of the Thermometers in the N, W, and V Magnetograph Boxes.

† The times are those of the Declination and Dip observations only. The Horizontal Force values given refer to the mean time of the Declination observations, being derived by a combined use of the actual observations and curve measurements.

‡ Observation with Dover Dip Circle No. 74 in West Hut.

* Mean of the Corrected Readings of the Thermometers in the N, W, and V Magnetograph Boxes.

† The times are those of the Declination and Dip observations only. The Horizontal Force values given refer to the mean time of the Declination observations, being derived by a combined use of the actual observations and curve measurements.

XLI.—READINGS OF THE NORTH COMPONENT OF TERRESTRIAL MAGNETIC FORCE

Eskdalemuir. (X.)

NOVEMBER, 1917.

This was the quietest month of the year, and, indeed, rather suggested a November in a quiet year. It presented very few features of interest. The most disturbed day was the 12th. A doubtful sudden commencement is shown at 7^h 39^m on that day, but was followed by no considerable movements. The changes in V were practically all above the undisturbed value. On N a prominent peak is shown at 16^h 26^m. Very few cases of pulsationary movement occurred beyond those noted between 1^h and 2^h, and 20^h to 21^h on 6th, and 19^h to 20^h, 23^h to 24^h on 25th.

* Mean of the Corrected Readings of the Thermometers in the N, W, and V Magnetograph Boxes.
† The times are those of the Declination and Dip observations only. The Horizontal Force values given refer to the mean time of the Declination observations, being derived by a combined use of the actual observations and curve measurements.
‡ Doors of East Room of Magnet House left open.

$-\Delta Y$ (or ΔW). L—WEST COMPONENT (all days except Jan. 4, May 24, 25, Aug. 9, 10, 13, 14, Dec. 14, 16).

ΔZ (or ΔV). LI.—VERTICAL COMPONENT (all days except Jan. 4, May 24, 25, Aug. 9, 10, 13, 14, Dec. 14, 16).

\bar{x} and n mark respectively the mean maximum and minimum hourly values in each month or season. The $-$ over the n denotes that the value to which the letter is prefixed is to be taken with the minus sign.

TERRESTRIAL MAGNETISM.

LII.-LIV.—DIURNAL INEQUALITIES OF THE MAGNETIC COMPONENTS, DECLINATION (D.), INCLINATION (I.), AND HORIZONTAL FORCE (H).

Eskdalemuir.

Mean Hourly Values, Greenwich Mean Time, for the Months, Year, and Seasons.

1917.

LXIV A.—HARMONIC COMPONENTS OF THE DIURNAL INEQUALITY.

Values of c_n, a_n in the series $\sum c_n \sin(15nt^\circ + a_n)$, t being Mean Local Time reckoned in hours from midnight.

Eskdalemuir.

(Longitude of Eskdalemuir Observatory, $3^{\circ} 12' W.$)

Note.—To obtain the phase angles for midnight, Local Apparent Time, the corrections ϵ , 2ϵ , 3ϵ , 4ϵ must be added to a_1 , a_2 , a_3 , a_4 respectively. The mean values of ϵ for the several months are:— $-2^{\circ}5$, $-3^{\circ}6$, $-2^{\circ}1$, $+0^{\circ}1$, $+1^{\circ}0$, $-0^{\circ}1$, $-1^{\circ}5$, $-1^{\circ}0$, $+1^{\circ}4$, $+3^{\circ}6$, $+3^{\circ}8$, $+1^{\circ}0$.

LXVII.—MEAN MONTHLY AND ANNUAL VALUES OF TERRESTRIAL MAGNETIC ELEMENTS AT
THE METEOROLOGICAL OFFICE OBSERVATORIES, 1917.

* Values for 1914 are from the first four and the last four months of the year only.

† Kakioka is the new magnetic observatory to replace Tokio. It is stated that values for Tokio may be deduced from those for Kakioka by adding -5° 5' to D, 265° γ to H, -48° to V.

NOTES ON THE METEOROLOGICAL SUMMARIES.

The outstanding feature of the year 1917 was the prolonged cold in the early months : it was also notable for unprecedented downpours of rain in June, for a very wet August, a stormy October, and a cold December. At Kew Observatory, Richmond, snow fell on no less than thirty-eight days in the first four months of the year and there were 70 ground frosts. Temperature remained well below normal until the middle of April. The thunderstorm of June 16th was noteworthy as giving the heaviest rainfall on record for London, 118 mm. having been recorded at Campden Hill, Kensington, in the remarkably short period of two hours. At Kew Observatory 43 mm. were recorded. More widespread rain was associated with the passage of a small depression which passed along the South coast of England on June 28th and 29th and was the occasion of the heaviest fall ever recorded in a day in the British Isles, viz. 250 mm. at Bruton, Somerset. At Kew Observatory the amount measured was 31 mm.

At Eskdalemuir severe weather lasted until well into April. The temperature in the screen on the night of April 1st was $258\frac{1}{2}^{\circ}\text{a}$, the lowest on record for Scotland for the month. The snow, which was as deep as 70 cm. in places, did not disappear until April 18th. In a gale, which occurred in the early morning of October 25th, a gust of 40 metres per second was recorded by the Dines tube-anemograph, the first time such a wind speed has been reached at this Observatory.

At Aberdeen the same dates are conspicuous ; the gust of 37 metres per second at this Observatory on October 25th is also the highest on record for the station.

At Valencia Observatory, Cahirciveen, the great snowstorm which visited Ireland at the beginning of April, though not so severe as at places in the counties to the North and East, is marked by the entry of hail with or without snow in the register on six consecutive days and may be regarded as the most important meteorological event of the year.

In these Meteorological Tables the normal diurnal variation for the month of each element is shown, together with the departure of the 1917 values from the normal. The 1917 values themselves can be read off by re-adding these differences. The values so found are averages for the months ; the individual readings from which the averages are derived are available for reference at the Meteorological Office. For the years 1874 to 1886 and 1900 to 1913 such hourly readings were published *in extenso*. For the years 1869 to 1880 and 1887 to 1899 five-day means were printed.

For the observatories at Richmond, Cahirciveen, and Aberdeen the normals for Barometric Pressure, Air-Temperature, and Rainfall refer to the forty-five
HOURLY VALUES, 1917.

years, 1871–1915; those for Wind Speed and Sunshine to the thirty-five years, 1881–1915; and those for Relative Humidity to the years 1886–1915. In the case of Eskdalemuir,* the “normals” are all for the five years, 1911–1915. For Falmouth only Rainfall and Sunshine are now tabulated. The normal diurnal variation of the other elements at Falmouth for periods ending in 1910 is given in previous volumes.

The tabulated values of pressure, temperature, and relative humidity refer to the exact hour by Greenwich time. The values of mean wind speed and of rainfall refer to the 60 minutes centered at an exact hour G.M.T. The duration of sunshine is given as a decimal fraction of the 60 minutes centered at an exact hour by Local Apparent Time. The difference between Local and Greenwich Time can be ascertained from the table on page 7.

In the tables for pressure, temperature, and relative humidity, values at 0 h and 24 h are both given. The small difference between these is due to the fact that the readings at the midnights with which a month opens and closes are in general different. In estimating the mean of all the readings for the month these first and last readings are given half-weight.

Particulars of the methods of tabulation and of the instruments are published in the Introduction to Part IV., Section 1, of the *Year Book* for 1913 and in the *Annual Reports of the Meteorological Office for the Years 1867 and 1869*. The barographs and the thermographs with dry and wet bulbs are photographic; the speed of the wind is recorded by cup-anemometers, except at Eskdalemuir, where a tube-anemometer is used for the hourly tabulations; the rain-gauges in use are of Beckley’s pattern; the duration of bright sunshine is measured by the Campbell-Stokes sunshine-recorder.

The values in the tables have been expressed throughout in units based upon the C.G.S. system; the following table shows the actual units employed for the different elements:—

| Element. | Unit. | Corresponding Units used previously or in other Countries. |
|----------------------------|----------------------------------|------------------------------------------------------------|
| a. Barometric Pressure. | Millibars. | Inches or Millimetres of Mercury. |
| b. Temperature of the Air. | Degrees Absolute. | Degrees Fahrenheit or Centigrade. |
| c. Relative Humidity. | Percentages
(100=Saturation). | Percentages
(100=Saturation). |
| d. Velocity of the Wind. | Metres per Second. | Miles or Kilometres per hour. |
| e. Rainfall. | Millimetres. | Inches or Millimetres. |
| f. Sunshine. | Hours. | Hours. |

Tables for the conversion from one set of units to the other were given with the notes for 1913. They will be found in the *Computer’s Handbook*.

(a) The barometer readings are obtained from the hourly tabulations of photographic records from similar apparatus at all the observatories. Due allowance is made for the variation of gravity with latitude. The pressures refer to station-level. Tables for “reduction” of pressure to sea-level are printed in the Introduction to Part IV., Section 1, of the *Year Book* for 1913.

* Brackets are used in the Tables to call attention to the illegitimate use of the word “normal.”

The barographs* at Richmond and Aberdeen have remained unchanged throughout the whole period. The site of Valencia Observatory was changed from Valencia Island to Cahirciveen, County Kerry, on March 23rd, 1892, the change in the height of the cistern of the barometer being from 7.0 m. to 13.7 m. The site of the observatory at Falmouth was changed in May 1885, the change in the height of the cistern of the barometer being from 64.3 m. to 55.8 m. Account has been taken of these changes of position in calculating the pressure normals for the period 1871–1915, and the values given correspond with the present positions.

(b) *Temperature of the Air.*—Temperature is expressed in degrees absolute on the Kelvin Scale. The value of a degree is the same as on the centigrade scale, but the zero is taken to be the absolute zero of temperature, 273° C. below the normal freezing-point of water.† The practice of indicating “degrees absolute” by “*a*” instead of by °A has been adopted recently. Thus the temperature of the freezing-point of water is written 273*a*. Conversion from the centigrade to the absolute scale is a simple addition or subtraction. Tables for converting from the Fahrenheit to the absolute scale are given in the *Computer’s Handbook*.

The temperatures shown for all four observatories have been derived from the tabulation of photographic records from similar mercurial thermometers. At Eskdalemuir the thermometer screen is a large hut with louvred sides. At the other observatories the screen is on the north wall of the observatory building. At Kew Observatory, Richmond, the height of the thermometers above ground is 3.0 m., and the bottom of the screen is open. At Aberdeen the observatory is in the tower of King’s College, and the screen is at a considerable height, 12.5 m. above ground. At Valencia Observatory, Cahirciveen, the height of the thermometers is 1.2 m.; in computing the normal values for the station no allowance has been made for the change in site in 1892.

It should be noted that the diurnal range of temperature, as determined by thermometers exposed in a north wall screen, is appreciably less than the range in a Stevenson screen in the open.

Before 1915 the tabulated values were taken directly from the curves, and were not corrected for the difference between the curve readings and the observations of the control-thermometers. The differences were always small, and it is not supposed that appreciable errors in the normal values have been introduced on this account. From 1915 methods have been adopted which eliminate this source of error.

The prolonged cold at the beginning of the year is a conspicuous feature of the temperature table. The largest deficit as compared with the normal is shown at Eskdalemuir, no less than 3.5*a* in February, but the average utilised as the “normal” is derived from only five years’ observations in this case. At Richmond the deficit was 2.4*a* in February, 2.1*a* in March and 2.5*a* in April. In connection with the low temperature in February it is of interest to notice that in

* The ultimate standard barometers at Kew Observatory have not been moved since they were set up in 1855 and 1860 respectively. The barometer used at this observatory to control the barograph readings is standardised with reference to these instruments. The barometers formerly in use at the other observatories depended on the same standards. The control-barometers now in use at these stations are provided with millibar scales certified at the National Physical Laboratory, Teddington.

† The propriety of this definition has been discussed by F. J. W. Whipple, *London Phys. Soc. Proc.*, vol. xxxi., 1919, p. 240.

spite of persistent dull weather, and less than half the normal amount of sunshine, the range of the diurnal variation, from 273·3 at 7 h. to 277·3 at 15 h., was more than half a degree above the normal.

(c) Relative Humidity is obtained from the tabulation of the photographic records of temperature combined with those of the wet-bulb thermometer. The thermometers are similar at all the Observatories; they have cylindrical bulbs about 4 inches long. The values of the humidity are calculated by the use of the Meteorological Office tables, which are based upon Glaisher's factors.*

The means for Richmond, Eskdalemuir, and Cahirciveen are obtained from the hourly values of humidity for each day; the means for Aberdeen are calculated from the mean hourly values for the month of the dry- and wet-bulb temperatures.

Mention should be made here of a difficulty inherent in the psychrometric method of determining the relative humidity of the air. The depression of the wet-bulb reading depends, not only on the amount of vapour present in the air, but also on the strength of the wind blowing past the thermometers. The tables in use for computing the humidity take no account of the wind, and the results are, therefore, open to criticism.

(d) Wind.—The speed of the wind is obtained from the records of similar Robinson anemographs at Richmond, Cahirciveen, Falmouth, and Aberdeen, but at Eskdalemuir the records are made by a Dines Pressure-tube instrument. Anemographs of the latter type are also in operation at the other observatories and the charts are used in other publications of the office, e.g. in the *Monthly Weather Report Annual Summary*.

The records from instruments of the two types, exposed at the same place, give approximately the same values for the mean speed.

More serious than any imperfections in the anemometers themselves is the difficulty in determining the relation between the wind which crosses the Observatory at a particular height and the general flow of air in the neighbourhood. In the extreme case of the anemometer at Falmouth, the recorded speed is probably only half of what would be measured at the same height above ground in open country. The anemometer at Cahirciveen is on a tower at the NE corner of the main building, so that the exposure is less free for winds between SE and SW than for other directions.

The normal daily variation of wind-speed at moderate heights shows † a maximum in the middle of the day and a minimum at night. The ratio of the daily range to the mean speed is greatest at inland stations. The following values of this ratio are derived from the normals for the whole year :—

| | | | |
|---------------------|-----|------------------|-----|
| Cahirciveen | .28 | Aberdeen | .34 |
| Eskdalemuir | .47 | Richmond | .57 |

(e) Rainfall.—The tables give the mean values of the hourly measurements

* See *Computer's Handbook*, Section I.

† Cf. G. I. Taylor, "Phenomena connected with Turbulence in the Lower Atmosphere," *Proc. Roy. Soc., A.*, 1917, vol. xciv., p. 137.

for each month, *e.g.* the value entered to noon is the mean of the amounts which fall between the hours of 11 h 30 m, and 12 h 30 m during the month.

For the purpose of this table the rainfall day is to be regarded as beginning at 0 h 30 m.

There is reason to believe that the figures given for the rainfall at Cahirciveen in 1915 and 1916 were too high by nearly 5 per cent.*

The fluctuations in the hourly values for rainfall are remarkable. Such irregularities are to be expected, however, as a very heavy fall of say 30 mm. in a single hour of one day raises the annual mean for that hour by 0·1 mm., *i.e.* practically doubles it.

(f) *Sunshine*.—The duration of bright sunshine is obtained by the Campbell-Stokes sunshine-recorder and is therefore measured by the burning or scorching of a blue card by the focussed sunlight. The method of expressing the results is similar to that adopted for rainfall. The values are given in hours and are obtained by dividing the totals for each month by the number of days in the month.

Accuracy of Means.—The computation of mean hourly values for the tables has been carried to one decimal place beyond the last figure given by the individual readings. On account of unknown zero errors of the thermometers and barometers, and various defects of the anemometers, rain-gauges, and sunshine recorders, this refinement, regarded as determining the values for particular hours, is not justified, but the inclusion of the additional figures facilitates the study of diurnal variation.

Possible Systematic Errors.—The mean values as shown in the tables are known to be subject to certain small systematic errors incidental to the methods of recording and tabulating the various elements. The allowances which should be made to eliminate such errors as far as possible are under investigation, no such allowances have been made in the present volume.

One source of error was brought to light owing to the publication by Mr M. M'Callum Fairgrieve of a paper † entitled "A possible Two-hourly Period in the Diurnal Variation of the Barometer." The time-marks on the photographic barograms occur at intervals of two hours, alternate readings being taken at a time-mark and halfway between two time-marks. Owing to the difficulty in making the readings in the two categories quite consistent, a small systematic error equivalent to an apparent oscillation of pressure with a period of two hours affects the results. Similar small effects of the method of tabulation can be traced in the tables of temperature and humidity.

The errors are comparable with 0·005 mb. for pressure and 0·02 a for temperature.

It may be mentioned here that from January 1st, 1918, time-marks on the instruments in question have been made half-an-hour before each even hour instead of at the hour, so that the systematic error cannot recur.

Harmonic Analysis.—The systematic analysis of the records of pressure and temperature of the seven observatories of the Meteorological Office by means of the beautiful harmonic analyser invented by W. Thomson (Lord Kelvin) was a notable enterprise of the period 1871–1882. The results for each month of these

* See *Hourly Values* 1916, p. 68.

† *Journal of the Scottish Meteorological Society*, 1913, p. 158.

years are published in *Harmonic Analysis of Hourly Observations of Air Temperature and Pressure at British Observatories: Official Publication*, No. 93. This volume contains also the harmonic components for the average diurnal variation in the several months for the same period.* Corresponding data for longer periods have not been published by the Office. The annual mean diurnal variation of pressure at the Observatories has been analysed, however, for these *Notes* for the last few years. Results for 1917 are set out below, the normals for the older observatories being for 1871–1915, those for Eskdalemuir for 1911–1915:—

| Observatory and Period. | Amplitude in Millibars. | | | | Phase, Greenwich Mean Time. | | | | | | | | Phase, Local Mean Time. | | | | |

| Cahirciveen (Val.Obs.) | | | | | | | | | | | | | | | | | |
| 1917 . | ·106 | ·311 | ·026 | ·010 | 137·0 | 20 52 | 130·0 | 10 40 | 345·2 | 2 19 | 332·9 | 1 57 | 147·3 | 150·6 | 16·1 | 14·1 | |
| ,, Normal . | ·151 | ·307 | ·034 | ·004 | 177·8 | 18 9 | 130·9 | 10 38 | 331·9 | 2 37 | 42·3 | 0 48 | 188·1 | 151·5 | 2·8 | 83·5 | |

The notation is explained by two alternative formulæ for the inequality in question:

$$P_1 \sin (15t + A_1)^\circ + P_2 \sin (30t + A_2)^\circ + P_3 \sin (45t + A_3)^\circ + P_4 \sin (60t + A_4)^\circ + \dots$$

and

$$P_1 \cos 15(t - T_1)^\circ + P_2 \cos 30(t - T_2)^\circ + P_3 \cos 45(t - T_3)^\circ + P_4 \cos 60(t - T_4)^\circ + \dots$$

Here t is the time elapsed in hours since midnight and T_1, T_2, T_3, T_4 are the times of maxima of the four harmonic terms. The times of the corresponding minima differ from those of the maxima by twelve, six, four, and three hours respectively. While it has been convenient to record all the times to minutes this degree of accuracy can hardly be claimed.

It is of importance to note that whilst the 12-hour term is known to be fairly consistent throughout the year, the other terms are subject to very large changes from month to month.

It may also be mentioned that the "normal" values of the P 's refer to the normal diurnal variation. The average values of the P 's for individual years would naturally be greater.

* The results have been discussed recently by Dr. C. Chree, *Q. J. R. Met. Soc.*, xliv., 1918, p. 99.

ADDITIONAL INFORMATION.

For a general account of the weather of the year, reference should be made to the Annual Summary of the *Monthly Weather Report*. Daily readings at Richmond, Cahirciveen, and Eskdalemuir are published in the *Geophysical Journal*, corresponding data for Aberdeen in *Daily Readings at Meteorological Stations of the First and Second Orders*. A summary of the monthly values at each of the four observatories is to be found in the Annual Supplement to the last-named publication.

Climatic diagrams based on the average hourly values up to 1910 are given for Aberdeen, Cahirciveen, Falmouth, and Richmond in *The Weather Map*.

Graphs of diurnal variation of temperature at the same observatories for the period 1871 to 1895 are given in *Temperature Tables for the British Islands*. The corresponding pressure-graphs are reproduced in a paper by R. H. Curtis.*

Normal values for various elements are given in *The Book of Normals* which is in course of publication.

* *Q. J. R. Met. Soc.*, xxvi., 1900, p. 1.

TERRESTRIAL MAGNETISM :—I. NOTES ON THE MANAGEMENT
OF THE INSTRUMENTS AT KEW OBSERVATORY, RICH-
MOND, AND ON THE CORRESPONDING TABLES, 1917.
By C. CHREE, Sc.D., LL.D., F.R.S., SUPERINTENDENT.

The magnetograph has continued in regular operation throughout the year, and absolute observations of declination, dip and horizontal force have been taken usually once a week. The results of the absolute observations have appeared month by month in the *Geophysical Journal*.

On January 8th a scale value determination of the horizontal force gave 1 mm.=6·2 γ. After this determination the position of the horizontal force magnet was slightly altered, by means of the torsion head, to allow for the change of declination that had occurred since 1914. Thereafter a second scale value determination was made which gave 1 mm.=5·9 γ. This was checked several times in the course of the year, and was found to remain unaltered.

On January 10th a scale value determination gave for 1 mm. on the vertical force trace $20\frac{1}{2}$ γ. The sensitiveness was increased on January 16th to 1 mm.=15·4 γ. Subsequent scale value determinations on June 4th and December 3rd gave respectively 17·8 γ and 16·0 γ for the value of 1 mm.

The scale value of the declination instrument remained as in previous years,

$$1 \text{ mm.} = 0' \cdot 87.$$

The base values of the curves were determined by means of the absolute observations. These were taken as in past years with the Jones unifilar magnetometer, using collimator magnet K.C.I. and declination magnet K.O. 90, and the Barrow dip circle No. 33 with $3\frac{1}{2}$ -inch needles. In the absolute observations of horizontal force use was made of the three deflection distances—22·5, 30 and 40 cms.—and values were calculated for the “distribution constants” P and Q from all the observations of the year combined. The values thus obtained of late years have been as follows :—

| Year. | P. | Q. | Mean Value at
22·5, 30, and 40 cms. of
$\log_{10}(1+Pr^{-2}+Qr^{-4})$ |
|-------|--------|-------|-----------------------------------------------------------------------------|
| 1910 | +0·882 | —1354 | 1·99939 |
| 1911 | +0·832 | —1377 | 1·99934 |
| 1912 | +0·749 | —1286 | 1·99937 |
| 1913 | +1·504 | —1528 | 1·99959 |
| 1914 | +1·226 | —1343 | 1·99958 |
| 1915 | +0·778 | —1245 | 1·99942 |
| 1916 | +2·962 | —2044 | 1·99996 |
| 1917 | +0·696 | —1236 | 1·99938 |

The large apparent change in P and Q in 1916 as compared with previous years was pointed out in last year's Report. It will be seen that the values for 1917 have reverted approximately to what they were in 1915. The cause of these changes remains obscure. Originally the observations made in 1917 were reduced employing the values obtained for P and Q in the previous year. The substitution of the values appropriate to 1917 entailed a reduction of 12γ in the calculated values of H. The results were, however, obtained in time to secure the publication of the corrected values in the *Geophysical Journal*.

If the apparent changes in P and Q since 1915 represent true changes in the distribution of magnetism in the magnets, either the change must have been mainly in the mirror magnet (the deflected magnet), or else such change must occur without any correspondingly large change of magnetic moment in the collimator (the deflecting magnet). A calculation of the magnetic moment (at 0°C) of the collimator magnet, from the combined December and January absolute observations since December 1909, gave, as the value appropriate to January 1st of consecutive years from 1910 to 1918, the following results : 649.26, 648.62, 647.57, 646.59, 646.13, 645.40, 644.47, 643.87, and 643.46. This shows a very slow decline, at a nearly uniform rate, and certainly would not suggest any very exceptional occurrence during the last three years.

As mentioned in last year's Report, the electrification of the London and South-Western Railway's line in the spring of 1916 caused a large increase in the local artificial disturbance, and the subsequent electrification of the North London line from Richmond to Broad Street presumably added to this. The increase of artificial disturbance is especially large in the case of vertical force, but as no diurnal inequalities have been published for that element since 1902 this is of minor consequence. In the case of the horizontal components D and H, the uncertainty introduced is mainly in instantaneous values ; the effect on mean hourly values even for individual days appears to be small. The publication of diurnal inequalities from the international quiet days has thus been continued.

Particulars of the magnetic "character" of individual days on the international scale "0" (quiet), "1" (moderately disturbed), "2" (highly disturbed), have been contributed quarterly, as in recent years, to Prof. van Everdingen at De Bilt, for inclusion in the international lists. Full details will be found in the *Geophysical Journal*. The accompanying table shows the number of days in each month to which the characters "0," "1," and "2" were assigned. It also gives for each month the mean of the "character" figures, treated as if ordinary arithmetical quantities. As there is a wide range in the disturbance to which any one figure is attached, these monthly means should be regarded as giving only a general indication of the disturbance prevailing.

| 1917. | Number of Days having Magnetic "Character." | | | Mean of
"Character"
Numbers. |
|-------------------------------|---------------------------------------------|------|------|------------------------------------|
| | "0." | "1." | "2." | |
| January | 7 | 19 | 5 | 0.94 |
| February | 9 | 15 | 4 | 0.82 |
| March | 16 | 13 | 2 | 0.55 |
| April | 12 | 15 | 3 | 0.70 |
| May | 13 | 15 | 3 | 0.68 |
| June | 16 | 9 | 5 | 0.63 |
| July | 18 | 9 | 4 | 0.55 |
| August | 14 | 8 | 9 | 0.84 |
| September | 14 | 15 | 1 | 0.57 |
| October | 12 | 12 | 7 | 0.84 |
| November | 19 | 7 | 4 | 0.50 |
| December | 14 | 10 | 7 | 0.77 |
| Year (totals and means) . . . | 164 | 147 | 54 | 0.70 |

The mean "character" figure for the year is somewhat below that for 1916, there being a decidedly smaller number of days of "character 1," and a greater number of days of "character 0." None of the magnetic storms of the year were exceptionally large, but there was very considerable disturbance on the following dates: January 4-5, February 15-16, June 24-25, August 9, 14, 15, 21 and 22, and December 16-17. On January 4-5 there was a range of 56' in D, and on December 16-17 a range of 408 γ in H. The disturbance of December 16-17 presented several features of interest which have been discussed in a special paper* by the Superintendent. The declination and horizontal force curves were tabulated on the five international quiet days a month, particulars of which are given in the accompanying table.

*List of Magnetic Quiet Days for 1917, as issued by the International
Commission of Terrestrial Magnetism.*

| | |
|---------------------------|-----------------------------|
| January 3, 15, 18, 28, 29 | July 6, 16, 17, 18, 20 |
| February 1, 9, 12, 13, 27 | August 5, 6, 19, 28, 29 |
| March 2, 3, 28, 29, 30 | September 1, 11, 23, 25, 26 |
| April 10, 11, 14, 20, 27 | October 16, 19, 20, 21, 22 |
| May 6, 8, 13, 19, 20 | November 9, 10, 15, 16, 23 |
| June 1, 2, 19, 20, 30 | December 10, 13, 22, 23, 31 |

The usual temperature correction, viz., 3.1 γ per 1a, has been applied to the horizontal force curves. In view of the continual small oscillations now usual in the traces, all the curves were smoothed. The non-cyclic changes shown in Table LXVIIA. have been allowed for in the usual way, *i.e.* by assuming them to come in at a uniform rate throughout the day.

Tables LXI. and LXII. give the diurnal inequalities of declination and horizontal force, after elimination of the non-cyclic change, for each month of the year, for the year as a whole, and for three seasons defined as in the Introduction. The letters *x* and *n* are attached to the maximum and minimum hourly values. The units employed throughout are 1' in declination and 1 γ (or 1×10^{-5} C.G.S.) in horizontal force. In the case of declination the minus sign means that the magnet points to the east of its mean position for the day.

* *Proc. Roy. Soc., A.*, vol. 94, p. 525 (1918).

Table LXIII. gives the algebraic difference of the extreme hourly values of Tables LXI. and LXII.

In the case of declination the monthly values of the ranges are all in excess of the corresponding ranges for 1916, except in the case of the two months April and May, and the mean excess for the twelve months is $1'4$. The excess appears in the case of all the inequalities for the seasons and the year, being especially large, $1'91$, in the case of winter.

In the case of horizontal force, on the average of the twelve monthly ranges, there is an excess of $2\cdot1\gamma$ for 1917 over 1916. There is also an excess in 1917 in the case of the ranges for the inequalities for the year, equinox and winter, the excess for winter being no less than $9\cdot4\gamma$. But in the case of summer the range for 1916 is somewhat the larger, and the same is true of the five consecutive months March to July. The two months April and May show the largest deficiency of range in 1917 in horizontal force, and they are also the two months in which there was a reduced declination range. These two months are also exceptional in the matter of non-cyclic change in horizontal force. It has a negative sign in May, a very unusual feature, and is abnormally large in April, being almost twice as large as in any other month. The mean of the non-cyclic changes in horizontal force, $+4\cdot0\gamma$, is decidedly above average; the corresponding mean for 1916 was only $+3\cdot0\gamma$.

Table LXVII. contains mean monthly and annual values of declination, inclination, horizontal force, north and west components of force, vertical force, and total force. The results for declination and horizontal force are derived from the curve measurements of the international quiet days. The inclination results are derived from absolute observations of dip, taken at an hour in the afternoon when the departure from the mean value for the day is small, and by utilising the diurnal inequalities of previous years an allowance has been made for this departure. The values of the other elements are derived by calculation from those of declination, inclination, and horizontal force.

Westerly declination continues to fall rapidly, at approximately the same rate as in recent years. Every month except September shows a decline on the previous month. Inclination shows a small rise, as during the previous two years, and horizontal force a decided fall. There is a very regular decline in the west component, as there has been of late years; the north component, on the other hand, seems to be nearly stationary. Vertical force and total force show a decline since 1916, but these elements are affected by larger uncertainties than the others, and the irregularities apparent when successive years' values are compared are doubtless in part at least of instrumental origin.

Table LXVIII. gives a list of the values of the magnetic elements at the observatories whose publications are received at Kew Observatory, including the latest data available up to 1917. Owing to the war the sources of information have been more restricted than usual. The values for the British Observatories for the years 1918 and 1919 are also shown in this table.

TERRESTRIAL MAGNETISM :—II. NOTES ON THE MAGNETIC OBSERVATIONS MADE AT THE VALENCIA OBSERVATORY, CAHIRCIVEEN, 1917. By L. H. G. DINES, M.A., A.M.I.C.E., SUPERINTENDENT.

Absolute observations of declination, horizontal force (H), and inclination were taken in general twice a month with the Dover Unifilar No. 139, and the Dover Dip Circle No. 118, at the same hours of the day on each occasion. The mean times of observation were 10^h 20^m for the declination, 11^h 37^m for the horizontal force, and 14^h 31^m for the inclination. In no case did the time of any individual observation differ from the mean by more than 6 minutes.

Only such observations of each element have been used as were taken at times when that element, as recorded by the Kew magnetographs, was subject to no abnormal disturbance.

As in former years the deflections of the mirror magnet were taken at two distances of the collimator magnet, and a single distribution constant P calculated from them.

This constant was determined from the mean of all the observations utilised for publication in 1917.

In general, for each complete observation, twelve readings of deflection were taken, the order being as shown in the following scheme in which e indicates "north end east," and w "north end west." Double weight was given to the w's in working up the results.

| | |
|------------------------------------|-------------------------------|
| Collimator on East Arm at 40 cm. ; | e, w, e. |
| " " | 30 cm. ; e, w, e. |
| " " | West Arm at 30 cm. ; e, w, e. |
| " " | 40 cm. ; e, w, e. |

Particulars of the individual observations will be found in the monthly numbers of the *Geophysical Journal*, the figures for which were also based on the value of the distribution constant determined as above.

Table LXVII. gives the observed mean monthly and annual values of declination, horizontal force, and inclination, and corresponding calculated values for the total force and the north, west, and vertical components.

TERRESTRIAL MAGNETISM :—III. NOTES ON THE MANAGEMENT AND MANIPULATION OF THE INSTRUMENTS AT ESKDALEMUIR OBSERVATORY, 1917. BY A. CRICHTON MITCHELL, D.Sc., SUPERINTENDENT.

The magnetographs at Eskdalemuir are arranged so as to record the three geographical components of terrestrial magnetic force, viz. :—the north component N (or +X), the west component W (or —Y), and the vertically downward component V (or +Z). This arrangement is effected, in the case of the N and W instruments, by imposing a twist on the bifilar suspension so as to bring the magnets into an azimuth approximately perpendicular to the direction of the components which they respectively measure.

The north and west magnetographs employed were, as in previous years, the Adie bifilar instruments, while the vertical magnetograph was that lent by the late Professor Watson. During the year no change was made in the suspensions or mountings of the instruments or in the position of any control magnet.

The constants of these instruments were as follows :—

| | North. | West. | Vertical. |
|-------------------------------------------------|----------------------------------------------|----------------|---------------|
| Time scale : 1 hour = | 15·6 mm. | 15·6 mm. | 15·6 mm. |
| Time marks | Every two hours ; end of mark at exact hour. | | |
| Error of time mark | Not more than ± 1 min. | | |
| Period of vibration | 13·9 secs. | 11 secs. | 7·4 secs. |
| *Logarithmic decrement | ·345 | ·572 | .. |
| Angular equivalent of 1 mm. on paper | ·00032 radian. | ·00033 radian. | ·0003 radian. |
| Twist of bifilar suspension | 35° | 90° \pm 5° | .. |
| Ratio length of bifilar suspension | 51 | 66 | .. |
| mean breadth of suspension | | | |
| Temperature coefficient per 1°. | -9γ | -2γ | +26γ |
| Direction in which marked pole points | West. | North. | .. |
| Azimuth of magnet | 269° 58' | 0° 8·5' | 346° |

The scale values were determined fortnightly in the manner described in the 1913 Notes. From overlapping means, the following values were obtained and employed in reducing the hourly readings of the curves.

| Month. | North Instrument.
γ per mm. | West Instrument.
γ per mm. | Vertical Instrument.
γ per mm. |
|---------------------|--------------------------------|-------------------------------|-----------------------------------|
| January | 4·97 | 5·34 | 4·34 |
| February | 4·99 | 5·33 | 4·31 |
| March | 4·99 | 5·33 | 4·12 |
| April | 4·96 | 5·35 | 4·11 |
| May | 4·96 | 5·36 | 4·12 |
| June | 4·95 | 5·36 | 4·15 |
| July | 4·94 | 5·34 | 4·46 |
| August | 4·95 | 5·33 | 4·63 |
| September | 4·98 | 5·34 | 4·64 |
| October | 4·98 | 5·37 | 4·45 |
| November | 4·97 | 5·38 | 4·36 |
| December | 4·97 | 5·35 | 4·40 |

* The logarithmic decrement is the natural logarithm of the ratio of the amplitudes of two consecutive swings on the same side of the zero position.

The apparent force in the direction of either of the suspended magnets due to unit force at right angles to its nominal direction was found to be of negligible amount. In consequence, no correction has been made on this account in the 1917 tabulations.

Absolute observations were made weekly, as a rule, in the eastern magnetic hut. Declination and horizontal force were determined on Pier No. 5 by the Elliot magnetometer No. 60, whilst dip was observed on Pier No. 6 by means of the Schulze inductor No. 103.

In the reduction of absolute observations of H, the values of $\log \left(1 + \frac{P}{25^2} + \frac{Q}{25^4} \right)$ were obtained for a given month by taking the mean for seven months including the given month as fourth of the seven. The values employed during the year were as follows :—

January, .00520; February, .00520; March, .00520; April, .00511; May, .00518; June, .00530; July, .00531; August, .00543; September, .00548; October, .00558; November, .00551; December, .00547.

The base line values employed were obtained from smoothed curves drawn through points given by observation. The curves are shown in Plate I. In that for the vertical component there are a number of discontinuities. The largest of these was due to the renewal of the calcium chloride dryer ; the others to disturbances in the position of the magnet system produced by too large deflections during scale tests.

Plate I. also shows the variation throughout the year of the temperature of the room in which the magnetographs are installed. The slight irregularities in this curve during the latter months of the year were produced by the main doors of the building being opened while some experiments on ventilation were being made.

The hourly readings are taken from the magnetograms by means of a ruled glass scale, the reading for a particular hour being that ordinate which is estimated to be the mean reading for an hour centering at the particular hour.

The non-cyclic correction has been eliminated in the usual manner from the diurnal inequalities.

The diurnal inequalities of declination, horizontal force, and dip have been computed from those of the geographical components by means of the formulæ—

$$\delta D = \frac{180 \times 60}{\pi} (\delta W \cos D - \delta N \sin D)/H,$$

$$\delta H = \delta N \cos D + \delta W \sin D,$$

$$\delta I = \frac{180 \times 60}{\pi} \cos I (\delta V \cos I - \delta H \sin I)/H,$$

where δD , δI are expressed in minutes of arc. The values of D, H, and I used in these formulæ for the particular month were the mean values given in Table LXVII.

The diurnal inequalities, for all classes of day, were computed to 0.01y and

afterwards rounded off to the nearest tenth of 1γ . The Fourier coefficients printed in Tables LXIV. and LXV. were computed from the unrounded values and afterwards rounded off.

The present volume does not include any reproduction of magnetograms obtained on highly-disturbed days, but, on application to the Superintendent, any person requiring these for the purpose of special investigation may be supplied with photographic copies.

TERRESTRIAL MAGNETISM :—IV. REVIEW OF RESULTS OF
MAGNETIC OBSERVATIONS AT ESKDALEMUIR DURING 1917.
BY A. CRICHTON MITCHELL, D.Sc., F.R.S.E., SUPERINTENDENT.

1. The following account summarises the principal results of the magnetic observations taken during 1917.

Reference may be made to the corresponding Review for 1915, and to *Notes on the Management of the Magnetic Instruments* in this and preceding volumes of the *Year Book*, for details regarding the instruments employed and the manner of reading the curves.

2. *Mean Annual Values of the Magnetic Elements.*—The following table gives the values for the year of the different elements. These are, in all cases, computed from the continuous records, standardised by means of absolute observations. The values of H, D, I, and T are deduced from those of N, W, and V. A comparison is made with the previous year.*

TABLE I.

| Year. | H. | D. | I. | N. | W. | V. | T. |
|--------|-------|----------|----------|-------|------|-------|-------|
| 1917 . | 16732 | 17° 16·3 | 69° 38·6 | 15976 | 4971 | 45093 | 48097 |
| 1916 . | 16756 | 17° 26·1 | 69° 37·6 | 15986 | 5020 | 45119 | 48130 |

The value of H, which has been falling since 1912, showed a further decrease, though not so great as in the previous year. Declination continued to diminish at nearly the same rate as in the previous years. Inclination rose by 1°·0, and, after its minimum in 1914, has now reached about the same value as it had in 1909. The geographical components and the total force all fell in value, N and W by amounts nearly the same as in the immediately preceding years, V by a smaller amount than usual.

The extreme values for N, W, and V are shown below, the signs > and < indicating that the trace was off the sheet.

TABLE II.

| Component. | Maximum. | | | Minimum. | | | Absolute Annual Range. |
|------------------|----------|-------------|----|--------------|-------------|------|------------------------|
| | Value. | Date, 1917. | | Value. | Date, 1917. | | |
| North | 16483 | d | h | m | <15630 | d | h m |
| West | 5232 | Aug. | 14 | 16 | 21 | Jan. | 4 23 32 |
| Vertical | >45382 | Aug. | 14 | 16 | 15 | Dec. | 16 21 14 |
| | | Dec. | 16 | { 17 20 } 35 | <44724 | Aug. | 9 { 23 35 } 55 |

* It may be of some interest to compare the results obtained at Eskdalemuir with those recently published by G. W. Walker in *The Magnetic Re-Survey of the British Isles for the Epoch January 1st, 1915 (London Roy. Soc. Phil. Trans., vol. 219, 1919)*. The values of N, W, V, H, and D from Walker's iso-magnetic charts are respectively 15,985γ, 5060γ, 45,665γ, 16,738γ, and 17° 37·6'; whereas the mean values for December 1914 and January 1915, as actually observed at Eskdalemuir, were respectively 16,005γ, 5100γ, 45,187γ, 16,798γ, and 17° 40'·7.

The annual range of the north and west components was thus much greater in 1917 than in 1916. That of the vertical component was nearly the same in the two years.

3. *Magnetic Character of 1917.*—The number of days in each month to which the character figures 0, 1, or 2 were assigned is given below.

TABLE III.—*Frequency of Magnetic Character Figures, 1917.*

| Character. | Jan. | Feb. | Mar. | Apr. | May. | June. | July. | Aug. | Sept. | Oct. | Nov. | Dec. | Year. |
|------------|------|------|------|------|------|-------|-------|------|-------|------|------|------|-------|
| 0 | 10 | 19 | 17 | 18 | 14 | 16 | 16 | 9 | 10 | 12 | 19 | 13 | 173 |
| 1 | 17 | 6 | 12 | 12 | 15 | 12 | 9 | 12 | 19 | 11 | 8 | 13 | 146 |
| 2 | 4 | 3 | 2 | 0 | 2 | 2 | 6 | 10 | 1 | 8 | 3 | 5 | 46 |

The mean character figure for the year was therefore 0·65 as compared with 0·74 in 1916.

As stated in last year's Review, the question of employing the sum (ΣR^2) of the squares of the daily absolute ranges on N, W, and V as an index of magnetic character has received considerable attention in recent years. It was pointed out that while the value of ΣR^2 could distinguish clearly between quiet days and disturbed days, it was uncertain whether it could be used to select the five quietest days in each month. The following table gives some information on this point. 5q days are the internationally selected quiet days; 5Q days are those on which ΣR^2 at Eskdalemuir has the five lowest values for the month. The table refers to 1917, and the unit for ΣR^2 is $1y^2$.

TABLE IV.

| Month. | Mean Value of ΣR^2 . | | Mean Day of Month. | | Number of Days common to 5q and 5Q. |
|---------------------|------------------------------|-------------|--------------------|--------------|-------------------------------------|
| | On 5q Days. | On 5Q Days. | For 5q Days. | For 5Q Days. | |
| 1917. | | | | | |
| January | 4303 | 3793 | 19th | 13th | 3 |
| February | 4737 | 3782 | 12th | 8th | 4 |
| March | 7979 | 6457 | 18th | 13th | 2 |
| April | 9176 | 7292 | 16th | 20th | 3 |
| May | 9624 | 7988 | 13th | 13th | 3 |
| June | 10952 | 9891 | 14th | 15th | 3 |
| July | 12555 | 10146 | 15th | 13th | 3 |
| August | 12655 | 10830 | 17th | 13th | 3 |
| September | 11319 | 8688 | 17th | 20th | 3 |
| October | 7179 | 5834 | 20th | 19th | 3 |
| November | 3240 | 2406 | 15th | 17th | 2 |
| December | 3370 | 2879 | 20th | 19th | 3 |

It thus appears that the quietest days at Eskdalemuir, judged by the ΣR^2 criterion, correspond in about three cases out of five with the internationally selected days. There need be no surprise that the proportion is not higher, for the 5q days are selected on the basis of estimates from a considerable number of stations in widely separated positions. But that a single station should give such a result indicates that if all stations submitted daily values of ΣR^2 , the selection could be made with tolerable certainty.

The next point for consideration is the division of the month into quiet, moderately-disturbed, and highly-disturbed days. The importance of any such division depends on the extent to which it is considered necessary that magnetic results should be tabulated for each such class of day, but this question cannot be discussed here. As an illustration of the value of ΣR^2 on days of different magnetic character, as assigned under the present international scheme, the subjoined table has been prepared.

TABLE V.

| Month. | Mean Value of ΣR^2 . | | |
|---------------------|------------------------------|--------------|--------------|
| | On "0" Days. | On "1" Days. | On "2" Days. |
| 1917. | | | |
| January | 7495 | 16579 | 290128 |
| February | 8721 | 21304 | 117938 |
| March | 9643 | 20473 | 53599 |
| April | 12136 | 30865 | .. |
| May | 10632 | 27574 | 80127 |
| June | 14071 | 26910 | 87717 |
| July | 13786 | 22016 | 94906 |
| August | 14392 | 21967 | 330219 |
| September | 11971 | 20208 | 124974 |
| October | 8083 | 24272 | 56629 |
| November | 4652 | 16540 | 45106 |
| December | 4083 | 15070 | 244578 |
| Year 1917 | 9796 | 21751 | 168806 |
| Year 1916 | 9262 | 23006 | 111444 |

Of course, the mean values for the year in the "2" day column will vary with the intensity of the larger magnetic disturbances of the year. But the figures for "0" and "1" days show that the standard of distinction between these days, measured by ΣR^2 , was fairly consistent for the two years considered. It may also be mentioned that if 14,000 and 40,000 be taken as the values for 1917, of ΣR^2 , which separate "0" from "1" days and "1" from "2" days respectively, we should have 178, 142, and 44 days of character "0," "1," and "2" respectively, as against 173, 146, and 46 days selected according to the international scheme. The dividing values thus taken are, of course, arbitrary, but it should be noted that 14,000 is about midway between the means of the "0" and "1" days, and 40,000 is about double the mean of the "1" days.

4. *Diurnal Inequalities.*—As in 1915 and 1916, diurnal inequalities for 1917 have been tabulated for (1) five international quiet days (2) for five disturbed days, and (3) for all days in each month. The details for each class of day are given in Tables XLIX. to LXF. Some of the results are exhibited graphically in Plates II. and III.

The quiet days selected under the international scheme were as follows:—

| | | | |
|----------|--------------------|-----------|--------------------|
| January | 3, 15, 18, 28, 29 | July | 6, 16, 17, 18, 20 |
| February | 1, 9, 12, 13, 27 | August | 5, 6, 19, 28, 29 |
| March | 2, 3, 28, 29, 30 | September | 1, 11, 23, 25, 26 |
| April | 10, 11, 14, 20, 27 | October | 16, 19, 20, 21, 22 |
| May | 6, 8, 13, 19, 20 | November | 9, 10, 15, 16, 23 |
| June | 1, 2, 19, 20, 30 | December | 10, 13, 22, 23, 31 |

The photographic records were complete for all the days in the list, and the inequalities deduced from them are given in Tables LV. to LX. These inequalities show, in general, an increased range as compared with those of 1916. The range in the mean inequality rose from $36\cdot6\gamma$ in 1916 to $42\cdot0\gamma$ in 1917 on the north component, from $40\cdot2\gamma$ to $47\cdot1\gamma$ on the west, and from $11\cdot9\gamma$ to $13\cdot8\gamma$ on the vertical. The N inequality range was greatest ($62\cdot9\gamma$) in August, and the W inequality range ($74\cdot1\gamma$) in July. These are the largest monthly values recorded since January 1911. They are due in large part to the almost continuously disturbed conditions which prevailed during these months. For example the Eskdalemuir records showed only one day in August which was even approximately a really quiet day. The December inequality in N was of a somewhat unusual type : the range being $28\cdot1\gamma$, fully thrice its value in a quiet year.

The diurnal inequalities for disturbed days were deduced from the records obtained on the following dates.

| | | | | | | | | | | | |
|----------|-----|-----|-----|-----|----|-----------|-----|-----|-----|-----|----|
| January | 4, | 5, | 12, | 22, | 23 | July | 2, | 13, | 22, | 29, | 31 |
| February | 15, | 16, | 18, | 19, | 20 | August | 9, | 10, | 13, | 14, | 21 |
| March | 4, | 5, | 8, | 21, | 25 | September | 2, | 5, | 9, | 19, | 30 |
| April | 5, | 6, | 9, | 16, | 26 | October | 3, | 13, | 14, | 28, | 29 |
| May | 1, | 2, | 3, | 16, | 28 | November | 12, | 14, | 25, | 26, | 27 |
| June | 7, | 13, | 23, | 24, | 25 | December | 8, | 16, | 17, | 18, | 26 |

Owing to the large absolute range of disturbance during the year, several cases occurred, among these days, on which the trace was off the sheet. These are noted by the symbols > or < in the tabulated hourly values, and further particulars are given in the *Magnetic Notes* under each month. Otherwise, the records are complete for all the selected days.

It will be noted that the days selected include five cases in which 3 successive days occur, nine cases of 2 successive days, and 27 days which stand apart. The distribution in this respect resembles that of the previous year, except that in 1916 one case occurred in which a group of 5 successive days was selected. It has again to be pointed out that although the selected days are those of large—and even those of largest—disturbance, and from that point of view are properly selected, there is reason to believe that the physical significance of events on two successive days may be very different. It may very well be that an analysis of first and second days of large disturbance would yield results of a character differing in more than mere amplitude. There is also need for investigation of such different types of disturbance as those of 27th August 1916 and 6th October 1916. Examples of both types occurred in 1917.

As a general rule, the inequalities for the selected disturbed days of 1917 resembled those of 1915 and 1916. There were, however, some exceptions worthy of mention. On the N component, the evening maximum, which is usually shown in winter months, occurred much earlier in 1917. The noon minimum at equinox was deeper than in the two previous years, but the afternoon maximum was not so pronounced. The afternoon maximum in summer was at least an hour in advance of the corresponding maxima in 1915, 1916. On the W component, there were no marked differences between 1917 and the two previous years. On the vertical component, the inequality range at equinox was much smaller in 1917, and there was also a postponement of both the morning minimum and the afternoon maximum. On the other hand, the 1917 summer range was much greater,

and the feebly-marked minimum about noon, quite noticeable in 1915 and 1916, was absent in 1917.

Compared with 1916, the inequality of all days in 1917 shows larger ranges in N and W but a smaller range in V. The monthly values of the inequality-ranges reached high figures in August (68·1 γ N, 71·4 γ W). The vertical inequality-range was lower than that of 1916 in March, April, and November.

5. *Harmonic Analysis of Diurnal Inequalities.*—The coefficients in the harmonic series which express the different inequalities are given in detail in Tables LXIV. and LXIVA.

Comparison of the two years 1916, 1917 cannot be expected to yield much information, but attention is drawn to the lower values in 1917, as compared with the previous year, of the phase angles of the 24-hour wave. On the north component, it is smaller for all classes of day and at all seasons except for summer on disturbed days and all days.

On the west and vertical components it is smaller for all classes of day and for all seasons. Taken over the whole year, this retardation amounts to about half an hour on the north component; to about the same amount (but larger on disturbed days) on the west and vertical components. The 12-hour wave in 1917, as compared with 1916, was accelerated on disturbed days on all three components, and retarded on quiet days for the north and west components.

Table LXIVA. also illustrates the effect of disturbance on the phase angles, and this is exemplified in the mean diurnal inequality for V. In 1917 the 24-hour wave on disturbed days was about $5\frac{3}{4}$ hours in advance as compared with that on quiet days. (For 1915 and 1916 the difference was about 5 hours.) This acceleration is not so marked on the horizontal components.

6. *Daily Range.*—The mean absolute daily range for each month of 1917 is given in the subjoined table, compared with the corresponding means for 1911–16. The figures are also expressed as percentage of the mean daily range for the year.

TABLE VI.—*Absolute Daily Range. Mean Monthly Values, 1917.*

| Month. | Mean Absolute Daily Range. | | | | | | Mean Daily Range expressed as Percentage of Yearly Mean. | | | | | |
|-------------|----------------------------|-------|-------|----------------|------|------|----------------------------------------------------------|-----|-----|----------------|-----|-----|

The mean range for 1917 was larger in all three components than in any year since 1911. This, however, was due to the large ranges recorded in August and, to a lesser extent, in December. The values for these months were quite exceptional.

In last year's *Review*, the frequency distribution of absolute daily range, according to different amounts, was given for each year since 1911. A comparison of the 1917 distribution with the mean for 1911–16 is given below.

TABLE VII.—*Frequency Distribution of Absolute Daily Range.*

| Range.
γ | Number of cases, 1917. | | | Percentage Distribution. | | | | | |
|--------------------|------------------------|-------|-----|--------------------------|----------------|-------------|----------------|-------------|----------------|

| 140–149 . . . | 1 | 11 | .. | 0·0 | 1·0 | 3·0 | 1·5 | 0·0 | 0·3 |
| 150–159 . . . | 5 | 4 | 3 | 1·4 | 0·8 | 1·1 | 0·6 | 0·8 | 0·3 |
| 160–169 . . . | 5 | 2 | .. | 1·4 | 0·7 | 0·5 | 0·5 | 0·0 | 0·3 |
| 170–179 . . . | 4 | 4 | 1 | 1·1 | 0·4 | 1·1 | 0·6 | 0·3 | 0·5 |
| 180–189 . . . | 2 | 3 | 3 | 0·5 | 0·8 | 0·8 | 0·5 | 0·8 | 0·3 |
| 190–199 . . . | 2 | .. | 1 | 0·5 | 0·4 | 0·0 | 0·4 | 0·3 | 0·4 |
| 200 and over . . . | 20 | 12 | 15 | 5·5 | 1·7 | 3·3 | 1·3 | 4·1 | 1·4 |

If the above data are represented graphically it is seen that the frequency curve for 1917 is displaced in the direction of greater range as compared with the 1911–16 average. This is the usual effect of a more highly-disturbed year. The N component curve for 1917 shows a hump corresponding with ranges of 90γ – 100γ , and a drop for 140γ – 150γ . The W component curve for 1917 reproduces certain peculiarities in the 1911–16 curve. Both have a point of contrary flexure in the part rising from the origin. Both show a drop in value on the descending portion, the 1917 curve at 120γ – 130γ , the 1911–16 curve at 130γ – 140γ , the vertical component distribution for 1917 is very close to that of 1911–16.

Table VIII. gives details of the principal magnetic storms recorded at Eskdalemuir during 1917. Compared with the corresponding table of the previous year, it shows a larger proportion of disturbances beginning with "sudden commencement."

As mentioned above, it has not been thought desirable to reproduce by lithography curves for selected storms. Photographic reproductions can be obtained by application to the Superintendent.

TABLE VIII.—*Principal Magnetic Disturbances recorded at Eskdalemuir, 1917.*

Where the beginning of a disturbance has been marked by a "sudden commencement," the serial number is followed by an asterisk (*), and the time entered in the second column is that of the sudden commencement. To the tabulated values of maximum and minimum the following have to be added:—

N, 15,000γ; W, 4000γ; V, 44,000γ.

ATMOSPHERIC ELECTRICITY :—POTENTIAL GRADIENT AT KEW
OBSERVATORY AND AT ESKDALEMUIR IN 1917. By
C. CHREE, Sc.D., LL.D., F.R.S.

At Kew Observatory the instruments in use and the observational conditions have remained the same as in 1916. With regard to Eskdalemuir, Dr Mitchell reports that the multiplier which converts millimetres of deflection on the electrogram to volts per metre in the open was found to remain fairly constant during the first six months of the year, averaging about 70. Several changes were made in the second half of the year, making the value of this muliplier very variable. For five days (August 25th–30th) a copper-zinc electrometer was used while the Dolezalek instrument was dismantled and cleaned. On October 29th, 1917 the needle of the electrometer received a violent displacement during disturbance following a snowfall. The multiplier from that date until readjustment on November 9th was 147.

From October 1917 a quantitative record of the rate of leak from the electrograph has been kept at Eskdalemuir. A Wulf electrometer is connected to the wire leading from the jet to the recording electrometer and the whole system is given a charge from a dry pile. The fall of the potential, V , is measured and $-\frac{d}{dt}(\log_e V)$ is computed. Taking the minute as unit of time the value of this coefficient is found to vary between .016 and .013. A value of .025 is taken as indication of defective insulation. With such a value the charge would be reduced by half in about 30 minutes.

Tables A, B, and C, page 64,* give the diurnal inequalities of electrical potential gradient for the months and seasons of 1917. As usual, maxima and minima are distinguished by the letters x and n respectively. Table A, referring to Kew Observatory, is based on selected quiet days, *i.e.* days on which there is no occurrence of negative potential—numbering ten a month. In March, to obtain the full number of “days,” it was necessary to take periods of 24 consecutive hours commencing at different hours of the day. The commencing hour was 0^h in two of these periods, 14^h on six, and 18^h in the remaining two periods. Separate allowance was made for the non-cyclic change in each of the three groups of “days.” There is no entry for March in the column headed “24—0” as the figure would, under the circumstances, have been meaningless. Even on the representative selected day the non-cyclic change must be regarded as in the main an accidental feature, depending on the weather conditions near midnight of the selected days. It is desirable to choose days which will keep it as small as possible, because its elimination proceeds on the hypothesis that it represents a gradual change introduced at a uniform rate throughout the 24 hours, whereas the way it actually comes in is uncertain. When the non-cyclic correction is similar in size to the

* For convenience of comparison with previous years the roman numbers for the Tables are retained.

range of the diurnal inequality, the same confidence cannot be felt in the inequality as when the correction is small. In Table A, December is the only month possessing a notably large non-cyclic change. The diurnal inequality in that month presents, however, no specially abnormal feature.

The mean value for the year in Table A is almost the mean of those for the three previous years, but is a little lower than the mean for 1916. The reduction as compared with 1916 arises from winter and equinoctial months. In three of the summer months and in the summer season the 1917 mean value is the larger.

The diurnal inequality at Kew Observatory shows differences in details throughout the year, but at all seasons two maxima and two minima are clearly recognisable. The afternoon maximum and the early morning minimum are usually the principal ones. In Table A, however, two months, June and September, have the principal maximum in the forenoon, and the same is true of the summer season. The diurnal inequality in June is distinctly abnormal, the afternoon maximum being hardly recognisable. This is mainly accountable for the maximum in the summer season appearing in the forenoon.

Tables B and C refer to Eskdalemuir. The 0a days on which Table B is based correspond fairly with the Kew quiet days. They are days free from negative potential, and having no variation of potential as large as 1000 volts in any hour. All possible days having the necessary characteristics are, however, included, so that the number of 0a days fluctuates a good deal from month to month. The number available for the year was 103, as compared with 84 in 1916. In the winter months 36 days were available as compared with only 16 in 1916. In spite of the enhanced number of days the non-cyclic changes in Table B rule rather high.

The mean value for the year in Table B is 31 volts in excess of the corresponding value for 1916. In winter the excess in 1917 is no less than 118 volts. In summer the 1916 mean value is slightly the higher. The phenomena are thus the exact opposite of those described at Kew Observatory.

The diurnal inequality at Eskdalemuir throughout the whole year shows only one prominent maximum and minimum in the day. If we take, for example, the summer inequality in Table B—the general features of which are very similar to those of the mean of the three previous years, though its amplitude is less—we see that from 7^h to 18^h the value is persistently below the mean for the day, while during the remaining hours it is persistently above the mean. There is a distinct maximum near midnight, and a distinct minimum near noon. If there is a secondary maximum and minimum, they are insignificant and obscured by the irregularities existent in data depending on a single year. The equinoctial inequality is obviously similar to that for summer, only the hours of occurrence of the maximum and minimum and the times of change of sign present themselves earlier in the day. In winter the type at first sight looks quite different, negative signs presenting themselves at the early hours when positive signs are prominent in summer. But on closer inspection it will be seen that the type is fundamentally the same, only there is a great change in the hours of the maximum and minimum and in the times when the changes from + to — and from — to + occur. The minimum in winter presents itself at an early hour in the morning, just as it does at Kew Observatory the whole year round. But the type of the winter inequality

at Eskdalemuir is quite different from that at Kew Observatory, showing practically no trace of a secondary maximum in the forenoon or a secondary minimum in the early afternoon. It will be convenient to speak of the summer and winter *varieties* of inequality at Eskdalemuir when we want to emphasise the difference between an inequality having the negative sign most prominent near noon and an inequality having the negative sign most prominent in the early morning. It will be seen that the winter variety is dominant in Table B in all four winter months, and also in March, and to a less extent in October. May, June, July, and September, on the other hand, exhibit the summer variety. The same is true of August, but the transition from minus to plus in that month presents itself abnormally late in the day, and in consequence the maximum is deferred until the early morning hours. A somewhat similar phenomenon presents itself in April. The inequality in that month is, from the ordinary point of view, quite abnormal, the minimum appearing near the ordinary hour for the maximum, and conversely. The peculiarities of the August and April inequalities make themselves felt in the diurnal inequalities for their respective seasons by reducing the ranges.

In the inequality for the year in Table B we have a superposition of the winter and summer varieties. The winter months' inequalities having the larger ranges, the consequence is that the diurnal inequality for the year has an unbroken sequence of negative values from 0^h to 15^h . But the influence of the summer months leads to a very rounded form of curve. Between 1^h and 13^h the voltage ranges only from $-19v$ to $-40v$, and the average of the thirteen departures from the mean for this interval is only five volts.

The 1a and 2a days, included in Table C, agree with 0a days in the absence of large rapid excursions, but show negative potential. They numbered 49 in 1917, as compared with 44 in 1916. The number of days in individual months, especially October and March, is so small that conspicuous irregularities in the inequalities are inevitable.

In every month except May the mean value is lower in Table C than in Table B. This is a natural consequence of the presence of negative potential in 1a and 2a days. The difference between the mean values is exceptionally pronounced in March. The range in the monthly inequalities is larger in Table C than in Table B in seven months out of the twelve, and in the average of the twelve months. This might be due to negative potential being especially frequent near the natural hours of minimum. If such, however, were the case, the excess in the range should also appear in the seasonal inequalities in Table C, which is not true of the year as a whole, nor of two seasons out of the three. Thus the phenomenon is more likely due to the reduced number of days available for Table C.

If there is a persistent tendency to a regular type of diurnal variation, with maxima and minima at fixed hours, and irregular departures from it are small, the range of the inequality derived from a number of days is but little less than the arithmetic mean of the absolute ranges of the included days. If, however, there is no one dominant type of inequality, or if, while there is such a type, large departures from it are of daily occurrence, the inequality range will naturally fall far short of the arithmetic mean of the absolute ranges, and the larger the number of days the more is this likely to be the case. When irregular departures from a dominant

type are large, the inequality derived in a single month from a small number of days does not have its accidental features smoothed away to the same extent as when a larger number of days are included. And when one combines into seasons several months each containing but a few days, these irregular features will naturally tend to neutralise one another, and so lead to a relatively smaller range in the seasonal diurnal inequality.

It is thus of interest to compare the ranges of the seasonal diurnal inequalities in Tables A, B, and C with the corresponding arithmetic means of the ranges of the inequalities of the included months. The results obtained are as follows :—

$$(\text{Range in seasonal inequality}) \div (\text{Mean of ranges in included months}).$$

| Table. | Year. | Winter. | Equinox. | Summer. |
|-----------------|-------|---------|----------|---------|
| A | 0.77 | 0.94 | 0.81 | 0.84 |
| B | 0.50 | 0.93 | 0.64 | 0.80 |
| C | 0.39 | 0.35 | 0.57 | 0.39 |

We see that in winter the ratio approached unity in Tables A and B. The natural inference is that even in the monthly inequalities at that season, in days free from negative potential, the accidental features are too small to have a serious effect on the hours of occurrence of the maximum and minimum. A second inference is that the dominant type of the diurnal inequality is much the same for the four winter months. For, obviously, a marked difference of type in the inequalities natural to the included months would affect the seasonal inequality in the same way as a difference in the characteristics of the diurnal variation in individual days of a month affects the monthly inequality.

The equinoctial season is that where we should naturally expect to find least homogeneity in the type of the diurnal inequality, as the climatological conditions in March and September are usually very different. But for quiet days at Kew Observatory the ratio for the equinoctial season is substantial, and only a trifle less than that for summer. In the case of the year, the reduction of the ratio from 0.77 in Table A to 0.50 in Table B is a natural consequence of the larger difference between the winter and summer varieties of variation at Eskdalemuir than at Kew Observatory. The smallness of the ratio at all seasons in Table C seems mainly due to the large accidental element that remains in the diurnal inequalities for individual months.

In the way the tables are formed the single day on which the October inequality in Table C depends has as much weight in the equinoctial and annual inequalities as have the six days on which the September inequality depends. If it were certain that the natural type of the diurnal inequality was closely alike for all the months of a season, there would be much to be said for allowing equal weight to the individual days, irrespective of the month to which they belong. If this were done in Table C, the single October day would have its weight reduced from $1/4$ to $1/15$ in the inequality for equinox, and the three February days would have their weight reduced from $1/4$ to $1/6$ in the inequality for winter. The consequent effect on the seasonal inequalities would be considerable.

The great differences that present themselves in the diurnal changes of electrical potential gradient on different days of the same month reduce the value that one naturally attaches to diurnal inequalities. It is obviously desirable to know whether in a specified month we have to do with a single dominant type of diurnal variation, from which there are on individual days accidental departures, or whether we have several fundamentally different types, each characteristic of a particular type of weather.

The large seasonal variation in the hour of minimum on 0a days at Eskdalemuir may throw some light on the causes operative in producing low potentials there.
